Speaking about pollen and pollination: I've had the idea that pollen taken from different parts of the flower may carry different characteristics/traits on the outcome.

Nature seems to place a challenge inside everything in nature. "When everything is possible, nothing is longer possible".

So according to this above, as an example: pollen taken from deep down from the inside of the tube of a flower may produce flowers with an even more narrow tube!?

I know this is speculation and will be next to impossible to claim something like this scientifically, but I find it an interesting subject! This idea is more of a philosophical character though.
