Even though the same genetic material is shared through the pollen, there is sort of a "tombola" in work, all pollen grains doesn't produce identical flowers.

That "tombola" function may be related to locality of the pollen grains.

interesting thought if individual flowers also affect this (like size, as you mention Sami). I had spontaneous mutations, or "freak flowers" occasionally (e g a yellow flower on a normally dark orange flowering hybrid) and I've saved pollen from that freak flower to test this. It is a difficult and time consuming task to make any conclusions from this though.
